Physics of the Giant Atom

Emad Eldieb
Chairman of Theoretical Physics
Quena University
Egypt
eeldieb@yahoo.com

Abstract: If a particle treated as charged sphere and then equalized its electrostatic energy with its rest energy \(m_0c^2\) then, on the same model we can treat a collection of charges as a particle. So,

\[(k \frac{e^2}{r_o}) (p \frac{r_o}{r}) = m_0c^2 + (0)\]

Where; \(p\) is the number of the protons inside a sphere with a radius \(r\), \(e\) is the magnitude of the charge in coulomb and \(k\) is the electric constant

Where also; the factor inside the big bracket = 1, while the small bracket of the right side is not absolutely empty.

Our work lies inside this small bracket.

INTRODUCTION

Our work is built on a proposal - which is in a separate next discussion would appear as common physics and not a proposal- says that; if the field is so great that the expected speed of the particles equal speed of light -and only if the expected speed equal speed of light- then the proposed factor; \(c_o\) would be introduced to prevent speed of the particles to reach speed of light as follow;

\[(c_o k) \frac{e^2}{r_o} \frac{\hat{p}}{\hat{r}} = m (v \sqrt{c_o^2}) \hat{\frac{2}{2}} = e^2 p \mu (c \sqrt{c_o^2}) \hat{\frac{4 \pi}{4 \pi}} r\]  \hspace{1cm} (1)

Where; \(k\) is the electric constant \(\equiv \mu c^2 / 4 \pi\). Consequently the angular momentum form would be;

\[m (v \sqrt{c_o}) \hat{d} = \hbar \sqrt{c_o}\]  \hspace{1cm} (2)

Where; \(d\) is the inter-particles distance = the reduced Compton wave length = \(\hbar / \pi \times 16 \text{ m}\)

The following intuitive equation of the rest mass of a particle like a proton has a field with expected \(v = c\)

\[k \frac{e^2}{r_o} = m_0c^2\]  \hspace{1cm} (3)

\[E_\omega^\omega = \frac{(k \frac{e^2}{r_o}) [1]}{m_0c^2} + (0)\]  \hspace{1cm} (3)

\[(k \frac{e^2}{r_o}) (p \frac{r_o}{r}) = m_0c^2 + (0)\]  \hspace{1cm} (4)

Where; \(m_o\) is the field equivalent rest mass = \(h / c \times r_o = m_o\) while, \(m_o\) and \(r_o\) are the inertial rest mass and radius of a proton (or of a neutron).

Where, the factor inside the big bracket equal one while, the factor inside the small bracket in the right side is not null.

The small bracket could be analyzed by introducing the factor \(c_o\) as follow;

\[(kc^2 \div r_o) [p \frac{r_o}{r}] = m_0c^2 + (E_\omega + Eg)\]  \hspace{1cm} (5)
\( (k_e^2 \div r_o) [p \div r] = m_o c^2 + [(e^2 \mu c^2 c_o \div 4\pi r) + E_g] \)  

Where; \( E_g \) is the gravitational energy per a particle, and the factor inside the big bracket of the left side equal one and the resultant of the two terms of the big bracket of the right side equal zero.

The above last equation is the electric sub-sphere form of Compton sphere.

This proposed Compton sphere is formed of a number of protons \( p \), distributed homogeneously among much more number of neutrons \( n \), with in-between particular distance equal the reduced Compton wave length \( d \); 

\[ d = h \div c \div m_o = 2.09 \times 10^{-16} \text{ m} \]

The neutrons sub-sphere of Compton sphere could be written on the same way as;

\[ E_c = [h^2 \div 2m] \left[ 3\pi^2 (n \div V) \right]^{2/3} = mc^2 \]

Where, \( n \) over \( V \) is the density of matter inside this sphere.

\[ E_c = m^2 c^2 + [E'_c + E_g] \]

\[ = m_o c^2 + (h^2 c_o \div 2m) \left[ 3\pi^2 (n \div V) \right]^{2/3} + E_g \]

\[ = m_o c^2 + (m_o c^2 c_o + E_g) \]

Compton sphere is -so-formed of two interfering sub-spheres with radius;

\[ r = (r_o d \div r_o) \text{ n}^{1/3} \]

The factor \( c_o \) is a proposed factor introduced inside (and only inside) Compton sphere whose speed of its particles is expected to equal speed of light. The factor \( c_o \) equals the rest mass of the average potential energy -in joule- of the ground state of Bohr model over Bohr radius \( d_b \).

\[ c_o = \left[ (k_e^2 \div d_b) \div c^2 \right] \div d_b = 1.08 \times 10^{-24} \]

It is clear that \( E_c \) is equivalent to Einstein equation of the rest mass of a particle like a neutron while, \( E'_c \) takes the form of Fermi like Compton energy.

Now we can call the positively charged Compton sphere as the giant proton, while the negatively charged one as the giant electron.

Our work would be divided into two chapters; in the first one we would study the orbit of the ground state of the giant atom where we would discover that it is typically the orbit of the first planet in the solar system.

Throughout the second section we will show that the common atomic laws would succeed to estimate many parameters of the solar system;

1- Speed and radius of the orbit of each planet

2- The elliptical orbits of the planets

3- The ratio between mass of the sun (\( M \)) to the summed masses of all the planets.

So, our work suggested that the solar system had begun its motion as units of giant atoms. Later on, the atomic model disappeared after it left behind the above mentioned parameters to refer to the past existence of the giant atomic model.

So, the giant charge had existence in the form of Compton state. Compton state had existence not by condensation of the particles but by a principle we called the equivalency.

Existence of such state needs to overcome the following problems;

1- Coulomb force which would not allow existence of much charges in a comparative narrow space like the giant charge

2- Pauli exclusion principle which never allow two typical fermions to exist in the same state.

3- Wave of matter and uncertainty principle which act against condensation of matter in such a state.
**DISCUSSION**

**Approach to the giant atom**

1- **The hydrogen atom like system (h.a..ls.)**

Consider an electron e, with a non relativistic mass $m_e$ and a proton -p- with a mass $m_p$ orbit each other.

The two body problem could be reduced as one body problem as;

$$\mu = m_e m_p \div (m_e + m_p)$$

$$m = m_e + m_p$$

If, $m_p >> m_e$

$$F_{cp} = m_e a = \mu a$$ where, $a = a_e - a_p$

If, $r = r_e - r_p$

$$k e^2 \div r = m_e (v_e) ^2 \div r_e = m_p (v_p) ^2 \div r_p$$

The lagrangian, $L_g$ could be written as;

$$L_g = [ m_e (v_e) ^2 \div 2 ] + [ m_p (v_p) ^2 \div 2 ] - U(r_e - r_p)$$

The angular momentum $L$

$$L = m_e v_e r_e + m_p v_p r_p \approx m_e v_e r_e = \hbar$$

$$r_e = r M_e \div m \approx r$$

$$R_p = m_p R \div \mu \approx M_e R \div M_e = R$$

$$R_e \approx m_p R \div M_e \approx R \div 1844$$

The ground state $\mid 0 \rangle$ could be described by the Hamiltonian $H$ in time dependent form as;

$$H = - (\hbar \div 2m) \frac{\partial^2}{\partial x^2} + (E - U) = i \hbar \frac{\partial}{\partial t}$$

The solution gives;

- Expected radius $< r > = 5.29 \times 10^{-11} m$
- Expected speed $< \nu > = 2.18 \times 10^6$ m/s

2- **The major atom; a proposed inversed atom**

Although it is a proposed system yet it is the mathematic base of the giant atom system. Suppose that we have a hydrogen atom like system (h.a.l.s) and we succeeded to bind its electron through imaginary energy with a number of neutrons $= \frac{m_p}{m_e} = 1836$ neutrons. And suppose –also- that this proposed binding energy $\geq$ the total energy between the proton and its orbiting electron such that the neutrons bound electron can orbit as one body. Once we can create this imaginary major atom we will notice that;

There would be shift of the centre of the masses towards the neutron bound electron.

There would be –also- respective relative shift from quantum to classic physics.

Let us study this inversed atom (i.a.) side by side with (h. a.l.s.) and let us use for the first the capital letters and for the second the small letters.

We did nothing except binding the electron with 1836 neutrons so;

$$k e^2 \div r = k e^2 \div R$$

$$R = r$$

From (13);

$$R_p = M_e R \div \mu \approx M_e R \div M_e = R$$

$$R_e \approx m_p R \div M_e \approx R \div 1844$$
Where, \( M_e \) is the mass of the 1836 neutrons bound electron = 1836 \((M_n \div M_p)M_p\)

\(=1844 \) times the mass of the proton. And where, \( \mu \) = the inverse of \((1 \div M_p + 1 \div M_e) = M_e \div 1845 = M_p \div 1.0005 \approx M_p\). Consequently;

\[ R = R_p = r \quad (17) \]

\[ v = v_p \]

From (14);

\[ ke^2 \div r = ke^2 \div R = M_p v^2 \quad (18) \]

The angular momentum \( L \) obeys;

\[ L = L_p + L_e = l \hbar \quad (19) \]

Where, \( l \) is an acquired inversed atom level number.

On substitution we get;

\[ v = 2.18 \times 10^6 \sqrt{(m_e \div m_p)} = 2.18 \times 10^6 \div 43 = 5.06 \times 10^6 \text{ m/s} \quad (20) \]

\[ l = 43 \quad (21) \]

We can get –also–; \( \lambda_o = \lambda \div 43 \)

\[ 2\pi R = l \lambda_o = l \lambda \div 43 = \lambda \]

(22)

Where; \( \lambda \) is the wave length of Bohr radius.

3- The critical anti-escape energy

If a sphere A is formed of number of protons \( p \), distributed among much more number of neutrons \( n \), and if A is \( R \) distant from another sphere B which is formed of the same number of charges but with opposite sign –electrons- distributed by the same manner among \( n \), and if no binding energy inside each sphere except the gravitational energy then we may have the following states of motions;

The particles \( p \), move as singled particles by the electric field leading to escape of the charges so;

\[(m, n) \text{ m G} / r < k (e, p)e / R \]

Where; \( r \) is the radius of the sphere A.

To prevent escaping or to make the centre of the spheres move toward each other or to make the electric energy distributed homogeneously among \( p \) and \( n \) then we need;

\[ 0.6 (m, n) (m, n) \text{ G} / r \geq k (e, p) (e, p) / R \]

To make the centre of mass of the sphere orbit –by the electric field- the other sphere then we need;

\[ D (m, n)^2 \text{ G} / r \geq k (e, p)^2 / R \]

Definition of \( D \) needs two steps;

If a particle orbits another one then we need;

\[(m, n)m / r \geq m(v_1)^2 / 2 \quad \text{ where } v_1 \text{ is speed of the orbit of the particle.} \]

\[ [2 (m, n) m]G / r \geq k (e, p) e / R \quad (23) \]

If the sphere A orbits the sphere B by the electric field then we need;

\[ 0.6 [2 \times 2(m, n)^2] G / r \geq (m, n)(v_o)^2 = k (e, p)^2 / R \quad (24) \]

\[ 2.4 (m, n)^2 G / r \geq k (e, p) / R \quad (25) \]

The factor 0.6 arises from integration throughout \( n \) particles as;

\[ E_g = - \int G \sigma (4/3) \pi r^2 \sigma 4\pi r^2 dr = (3/5) G M^2 / r \]

Where; the integration is defined from zero to \( r \) and where \( \sigma \) is the density.
Physics of the Giant Atom

The giant proton to prevent escape of its charges need;

\[ (m_n n) m_p G \geq (e p) k c_o \quad (26) \]

\[ (n/p) \geq e^2 k c_o / m^2 G \quad (27) \]

Where the mass of a proton \( m_p \approx \) mass of a neutron \( m_n = m \)

The giant electron needs;

\[ (n^3 / p^3) = [(n + p) 1844] \quad (28) \]

Where; \( p^3 \) is the number of the electrons in the giant electron = \( p \)

The giant proton to orbit the giant electron needs;

\[ 2.4(m n)^2 G / d n^{1/3} \geq (e p)^2 k / R \quad (29) \]

Where, \( d = \hbar / mc = 2.09 \times 10^{-16} \) m.

And needs;

\[ (m. n) v^2 = k (e p)^2 / R, \text{ or in the form;} \]

\[ m. (n + p) v^2 = k e^2 p / R \quad (30) \]

Solution of (29) and (30) gives;

\[ 2.4 (m n)^2 G / r \geq (m n) v^2 \quad (31) \]

Although equation (31) is a net result of equations (29) and (30) yet it gives a new meaning as a fundamental relation between \( n \) and \( v \). It gives a restricted relation between \( n \) and \( v \) (also \( p \) and \( v \)) so it could be written as;

\[ v^2 = (2.4m G / d) n^{2/3} \]

Where; \( d = h / mc \)

\[ v^3 = n (2.4mG / d)^{1/2} \quad (32) \]

It is useful to notice that any other equation gives mistake relation between \( n \) and \( v \). Equation (30) as example is not a restricted relation between \( n \) and \( v \) because \( R \) could be analyzed into factors related to \( n \) and \( p \) while equation (31) depends on \( d \) which is independent fundamental constant.

**4-The eccentricity \( e \) of the giant atom:**

The aphelion = \( R_p = (1- e) R \)

The perihelion = \( R_v = (1+ e) R \)

\[ (R_v + R_p) / 2 = R \quad (34) \]

From (33) and ((34); \( (v_v + v) / 2 = R \div R_p = 1 / (1 - e) \)

If, \( e = 0.21; \)

\[ (v_v + v)^2 = 1.26 \quad (36) \]

Where \( v_v \), and \( v \) are the maximum – at the aphelion- and average speeds respectively.

**THE GIANT ATOM STRATEGY**

If the above relations has infinite solution; the giant atom –forever- chooses the least amount so the giant atom rewrites the last mention inequalities as equalities.

The equality of equation (27) gives;

\[ n / p = 1.14 \times 10^{12} \quad (37) \]

Now the giant proton is 1844 times lighter than the giant electron so it would orbit it. If the orbit is not circular then the elliptical orbit would have maximum speed at the perihelion \( v_v \). Equation (32) guards against escape of the charges of the circular orbit with constant radius. The elliptical orbit needs to multiply equation (33) with a factor more than one. Later on we would see that this factor should equal \( 5 / 3. \)
\[ n \div p = \left( \frac{1.14 \times 10^{12}}{5/3} \right) = 1.9 \times 10^{12} \]  

(38)

Now the gravitational energy can act against this accidental but expected \( v_x \).

**THE HUGE CHARGE**

Here we have to focus on equation (30) which supplies us with the physical unit of the giant charge; let us call it the huge charge. The huge charge which appears in equation (30) is the smallest unit of the orbiting charge. It has a mass \( m_u \) and a matter wave length \( \lambda_u \).

\[ m_u = m \left( n \div p \right) \]  

(39)

\[ \lambda_u = \lambda \div \left( n \div p \right) \]  

(40)

where; \( \lambda \) is the wave length of Bohr radius.

Its angular momentum would be in the form;

\[ (m n \div p) \left[ (\lambda \div l) (p \div n) \right] v = l \hbar \]  

(41)

The circumference \( S \) of the giant orbit is the summation of the huge waves;

\[ S = \left( \frac{\lambda p}{n} \right) p = 2\pi R = \lambda \left( \frac{p^2}{n} \right) \]  

(42)

**THE INERTIA OF THE GIANT ATOM**

From equation (29) and from strategy of the giant atom;

\[ 2.4m^2 \left( \frac{n}{p} \right)^2 G^2 \left[ \frac{d}{(n/p)^{1/3}} \frac{p^{1/3}}{e} \right] = e^2 k / R \]  

\[ P^{1/3} = \left( n/p \right)^{5/3} R_p \div 1.08 \times 10^{20} \]  

(43)

Where; \( R_p \) is the radius of orbit at the aphelion.

From equation (30);

\[ m \left( n/p \right) v^2 = k e^2 p / R \]  

\[ p = m \left( n/p \right) (v_x)^2 R_p \div e^2 k = m \left( n/p \right) v^2 R \div e^2 k \]  

\[ p = 7.22 (n/p) R v^2 \]  

(44)

(45)

By dividing (45) over (43);

\[ P^{2/3} = \left( \frac{p}{n} \right)^{2/3} \left[ 7.22 (v_x)^2 \left( 1.08 \times 10^{20} \right) \right] \]  

\[ P = \left( \frac{p}{n} \right) \left( 7.8 \times 10^{20} \right)^{1/2} (v_x)^3 = \left( \frac{p}{n} \right) \left( 2.17 \times 10^{31} \right) (v_x)^3 \]  

(46)

From equation (20) and (36);

\[ (v_x)^3 = \frac{5.06 \times 10^7}{\left( 1.26 \right)^{2/3}} \left( 1.29 \times 10^{14} \right) 1.41 \]  

\[ p = \left( 1 / 1.9 \times 10^{15} \right) \left( 2.17 \times 10^{31} \right) \left( 1.29 \times 10^{14} \times 1.41 \right) \]  

\[ p = 2.07 \times 10^{33} \]  

(47)

(48)

(49)

\[ n = p / (n/p) = 2.07 \times 10^{33} \times 1.9 \times 10^{12} = 3.94 \times 10^{45} \]  

(50)

\[ p^2 / n = 1.09 \times 10^{21} \]  

(51)

From equation (44);

\[ R_p = \left( \frac{p^2}{n} \right) \left[ \left( e^2 / 4\pi \epsilon_0 \right) + m (v_x)^2 \right] \]  

(52)

\[ R = \left( \frac{p^2}{n} \right) \left( e^2 / 4\pi \epsilon_0 \right) \div m v^2 \]  

(53)

From the last equation or equation (42);

\[ R = \left( 1.08 \times 10^{21} \right) \left( 5.29 \times 10^{-11} \right) = 5.71 \times 10^{10} \ m \]  

(54)

**Notes;**

1- From (42) and (53);

\[ \lambda = 2\pi \left( e^2 / 4\pi \epsilon_0 \right) \div m v^2. \]  

Where \( \lambda / 2\pi \) = Bohr radius.
We have to notice that when R and v are related to each other in the same equation then we can write R and v or R_p and v_x as in equations (52) and (53) while if v related to p or n in the same equation (without R) then we have to write v_x as in equation (46).

So; \( n = \left[\left(1.14 \times 10^{12}\right)^{5/3}\right] \) to be meaningful in equation (29) the speed v should be written as;

\[
m(v_x)^2 = 4 \left(0.6 \text{ m}^2 \text{ G n}^{2/3}\right) \div d = 4 E_G = k \left(e^2 p\right) (p/n) \div R_p
\]

This form speaks about the least possible gravitational energy which binds a particle inside the giant proton to enable the whole sphere to orbit as one mass where this giant proton is formed –in this stage- of neutrons (no atoms) and consequently no binding energy inside the giant proton except this gravitational energy. Because of the orbit is elliptical so the giant proton must have enough neutrons to act against escape of its charges at the accidental maximal v_x of the elliptical orbit.

Now the giant proton to orbit its giant electron is formed of;

\[
p = 2.07 \times 10^{13} \quad n = 3.94 \times 10^{15}
\]

And has orbit with;

\[
R = 5.71 \times 10^9 \text{ m} \\
v = 5.06 \times 10^4 \text{ m/s}
\]

Later on –in a separate discussion- we would see that each a planet was formed of number of these giant charges then in a next stage and after beta decay and formation of atoms the inter-particles distances would increase and consequently the radius of the giant charge would increase which would lead –by equation 29- to inability of the unit to keep its charges which would lead to escape of the charges and consequently attraction and unification of the units to form the planet where Newton's laws would receive the file of the motion as the same R and v.

Actually the astronomic known radius of the orbit of the mercury planet is the same as our estimated R. Also its known natal orbit speed is as our estimation. This encouraged us to go on with the solar system. But before we go on we need to study the basic unit from which the giant charge is formed. We also need to ask if we can create such a unit so, the following discussion would be under the title the created giant charge.

**THE CREATED GIANT PROTON (C. G. P.)**

If many protons had formed a sphere then to apply our proposal we need;

The speed v of the proton = c and –also- we need; the rest mass \( m_o \approx \) the relativistic m

It is impossible to realize these two conditions except if we considered the equation of the rest mass is our need model such that;

\[
\left(\frac{k e^2}{r_o}\right) \left[1 \div \left(\frac{d}{r_o}\right) \left(\frac{n}{p}\right)^{1/3}\right] = m_o \cdot c^2
\]

(56)

Where the net result of the factors inside the big bracket equal one and where \( m_o \) is the field equivalent rest mass = \( \hbar / r_o c \equiv m_o \).

The equation (56) is the only form which can act against the pressure of \( p \), inside such sphere. This means that we can deal the left side of the equation as a field equivalent rest energy and –in the same time- as coulomb electric energy. So we can now estimate the number of the protons \( p \), just enough to make \( v = c \) and to make –in the same time– the net result of the factors inside the big bracket equal one.

Put; \( n/p = 1.9 \times 10^{12} \)

And; \( r_o = 2.09 \times 10^{-16} \text{ m} \)
And; \( m_\text{o} = m_e = 1.67 \times 10^{-27} \) kgm.

\[
p = 2.23 \times 10^9
\]

\[
n = 2.23 \times 10^9 \left( 1.9 \times 10^{12} \right) = 4.24 \times 10^{21}
\]

Once the condition is fulfilled (the field is so high that the expected \( v = c \)) then the factor \( c_o \) have to be introduced to prevent \( v \) to reach \( c \) as:

\[
E_e = k c_o p e^2 / r = m_\text{o} \left( c \sqrt{c_o} \right)^2 = 1.4 \times 10^{-34} \text{j}
\]

The gravitational energy \( E_G = 0.6 \) (m n) m G \( \div r \)

Put; \( n = 4.24 \times 10^{21} \) and \( r = d n^{1/3} \)

\[
E_G = 1.4 \times 10^{-34} \text{j}
\]

Equation (56) could be written as;

\[
\left( k e^2 / r_o \right) \left[ p^{2/3} \div \left( d / r_o \right) \left( n / p \right)^{1/3} \right] = m_\text{o} c^2 + \left[ 0 \right]
\]

Or could be written as;

\[
\left( k e^2 / r_o \right) \left[ p^{2/3} \div \left( d / r_o \right) \left( n / p \right)^{1/3} \right] = m_\text{o} c^2 + [E_G + E_e]
\]

\[
= m_\text{o} c^2 + \left[ m_\text{o} c^2 c_o + E_G \right]
\]

On the same way we can deal each neutron as follow;

**COMPTON ENERGY**

It is the Pauli term per a neutron \( E_c \) (Compton energy with introducing \( c_o \) of the created giant charge\(^3\)) which is opposed by the gravitational energy acting on each a neutron of the smallest giant proton which we called the created giant proton as follow;

Number of states \( N = (2/8) \left[ 4\pi n^3 / 3 \right] \)

\( E_c \) (Compton energy without \( c_o \)) = \( (\hbar^2 / 2m) \left( 3\pi^2 N / V \right)^{2/3} \)

where; \( V \) is the volume.

Since \( d = 2.09 \times 10^{-16} \) m, then the speed of a neutron = \( c \), so we have to introduce \( c_o \),

\( E_c = \left[ (\hbar \sqrt{c_o})^2 / 2m \right] \left[ 3\pi^2 N / V \right]^{2/3} \)

\( E_c \) of all neutrons = \( \int E_c dN = (3/5) E_c N \). where; the integration from zero to \( N \).

Dividing on \( N \) gives the average Pauli term per a neutron = \( E_i \)

\( E_i = (3/5) E_c \)

Put the density of states = \( N_i = N / V = n / V \) is the number of neutrons in the defined volume.

\( N_i = n \div (4/3) \pi (2.09 \times 10^{-16})^3 = 2.61 \times 10^{46} \text{ m}^{-3} \)

From (63), (64) and (65);

\( E_i = 1.4 \times 10^{-34} \text{j} \)

\( E_i = -E_G \)

Equation (63) could be written as;

\( E_c = (\hbar^2 / 2m) \left( 3\pi^2 N / V \right)^{2/3} + [E_i + E_G] \)

Where the result of the two terms of the big bracket = \( 0 \)

Or could be written as;

\( E_c = (\hbar^2 / 2m) \left( 3\pi^2 N / V \right)^{2/3} + [m_\text{o} c^2 c_o + E_G] \)
Physics of the Giant Atom

\[ E = m_o \cdot c^2 + [ m_o \cdot c^2 \cdot c_o + E_G ] \]  
\hspace{1cm} (72)

From (63) and (72) the total energy \( E \) per a particle (proton or neutron) = \( E \)

\[ E = m_o \cdot c^2 + [ m_o \cdot c^2 \cdot c_o + E_G ] = m_o \cdot c^2 + [0] \]  
\hspace{1cm} (73)

It is clear that \( n \) is much more than \( p \) therefore \((n - 2p)^2 \div n = n\)

Consequently, Pauli term (for all neutrons) = \((m_o \cdot c^2 \cdot c_o) \cdot n\)

From all above; - as the estimations showed as in equations (59), (60) and (68) – ;

\[ E' = E = E_G \]

This means that the created giant proton has residual energy equal zero as in (73).

In a coming discussion we would follow up two stages; in the first we would follow up the collection of the created giant protons to form the giant proton while in the second we will follow up the collection of the giant protons to form the planet.

**THE REST ENERGY OF THE CREATED GIANT CHARGE**

1- The equation:

\[ (k \cdot c^2 \div r_o) \cdot [p^{2/3} + (d / r_o) \cdot (n / p)^{1/3}] = m_o \cdot c^2 + [0] \]  
\hspace{1cm} is the key of the physics of the created giant charge.

2- \( m_o \) is not the real inertial rest mass -although it is equivalent to it- but it is the field equivalent rest energy = \( h \cdot \omega / c^2 \)

\[ = h / c \cdot d \]

3- Imagine a closed sphere with radius \( r \), obeying the shell theory then an electric field would obey;

\[ \frac{\partial^2 E}{\partial a^2} = - \sigma / \varepsilon_o \] where; \( \sigma \) is the density of the charges \( p \), and \( a \) is the distance from the centre to the defined point. The solution would be in the form:

\[ E = k \cdot c^2 \cdot p \cdot (3 - a^2 / r^2) \div 2r \]

This solution gives; \( E = E \) at the surface and \( E_o = 1.5 \cdot E \) at the centre.

At a defined point \( a = (0.5)^{1/3} \cdot r = 0.79 \cdot r \) the quantity of the charges \( (p') \) would obey;

\[ p' = p \cdot (a / r)^3 = p \cdot (0.5) \]

This gives -at the defined point \( a = 0.79 \cdot r \) - two potentials;

\[ m \cdot (v_1)^2 / 2 = k \cdot \sigma \cdot a^2 = k \cdot \sigma (0.79 \cdot r)^2 = 0.62 \cdot r^2 \cdot k \cdot \sigma \] where \( v_1 \) refers to motion toward the surface.

\[ m \cdot (v_2)^2 / 2 = k \cdot \sigma \cdot a^2 = k \cdot \sigma (0.79 \cdot r)^2 = 0.62 \cdot r^2 \cdot k \sigma \] where \( v_2 \) refers to motion toward the centre

This gives total potential = \( m \cdot v^2 = 2 \cdot (0.62 \cdot r^2 \cdot k \sigma) \)  
\hspace{1cm} (74)

This means that the created giant charge looks to the particles of the sphere as if they located in this defined point and if the half of the particles move toward the surface and the remainder of the other half move in the opposite direction with net motion equal zero although the potential = \( m \cdot v^2 \):

\[ v_1 \cdot v_1 = v_2, \ v_2 = v^2 \]

\[ v_1 + (-v_2) = 0 \]  
\hspace{1cm} (75)

4- A number \( u \) of particles each with a rest mass \( m_o \) when collect they do that by simple addition. If \( u = 8 \) then;

\[ \Sigma m_o = 8m_o \]. Also does \( m_o \). This means that;

\[ (k \cdot c^2 / r_o) \cdot [1] \cdot u^{2/3} \cdot u = u^{2/3} \cdot m_o \cdot c^2 \cdot u \] is error manipulation, the correct is;

\[ (k \cdot c^2 / r_o) \cdot [1] \cdot u = m_o \cdot c^2 \cdot u \]  
\hspace{1cm} (76)

This means that \( m_o \cdot c^2 \) per a particle is constant whatever the number of the units may be.
THE RESIDUAL ENERGY OF THE GIANT CHARGE

The residual or zero point of energy of such ground state lies inside the big bracket of equation (73) whose net result equal zero. When the created giant charges collect in the form of giant charge then we are in front of higher state of the particles inside this giant charge. The giant proton is formed of unit’s u, of the created giant proton.

\[ u = 3.94 \times 10^{15} \div 4.24 \times 10^{21} \]

Because of each of the electric \( E_e \) and the gravitational \( E_G \) energy is central and infinite while Pauli (Compton) \( E \) energy is finite so; the energy per a particle (either proton or neutron) = \( E \).

\[
E = m_v c^2 + [(u^{2/3} E_G + u^{2/3} E_e) + (u^{2/3} E_G + E)]
\]

(77)

Where, \( u^{2/3} E_G \) is much more than \( E \) of all the particles \( A \) of the giant proton = \( E_A \)

\[
E_A = m_v c^2 + A [(0) + (u^{2/3} E_G)]
\]

(78)

Where; \( A = p + n \)

It is clear that the definition of \( c_0 \) would be modified here to become; when the field is so high that the expected classic speed equal or exceed speed of light then this factor have to be introduced to prevent speed of the particle to reach c.

THE PHYSICAL CONCEPT OF THE FACTOR C_0

Quantitative Method;

From relativity;

\[
m c^2 = m_o c^2 + \Delta m c^2
\]

\[
m c^2 = m_o c^2 + m_o v^2 / 2
\]

\[
\Delta m c^2 = m_o v^2 / 2
\]

\[
m = m_o v^2 / 2c^2
\]

\[
mc^2 = (m_o c^2 / 2) (v^2 / c^2)
\]

If the medium was homogeneous with constant density

From above and equation (61)

\[
E_e = (m_o c^2 / 2) (A_u / A_x)^{2/3}
\]

(79)

Where; \( A_u \) and \( A_x \) are the number of particles of the unit in which \( E_G = E_e \) (the created giant charge) and number of particles – in Compton state- whose gravity gives the maximum speed c respectively as:

\[
0.6 A_x m^2 n G \div 2.09 \times 10^{-16} A^{1/3} = mc^2 / 2
\]

\[
A_x^{2/3} = 1.4 \times 10^{38}
\]

(80)

From (58);

\[
A_u^{2/3} = (4.24 \times 10^{21})^{2/3} = 2.6 \times 10^{14}
\]

(81)

From all above;

\[
E_e = m_o c^2 (2.6 \div 2.8 \times 10^{24}) = m_o c^2 (1 \div 1.08 \times 10^{24}) = m_o c^2 c_o
\]

(82)

Here the factor \( c_o = 10^{24} \div 1.08 \) appears as common physics.

Qualitative method;

From (12); the factor \( c_o = m_o / d_b = E_o \div c^2 d_b = 4.36 \times 10^{-35} / d_b \)

\[
m_o = E_o / c^2 = m (5.3 \times 10^{-5}) = m (2.9 \times 10^{6})
\]

(83)

International Journal of Advanced Research in Physical Science (IJARPS) Page 36
Where; \( m_e \) and \( m \) are the rest mass of the electron and neutron respectively.

But this proposed factor is introduced only when the field (electric) gives expected

\[
v = c \text{ as;}
\]

\[
E = E \cdot c_0 = m \cdot c^2 c_0
\]  

(85)

From above;

\[
E = m \cdot c^2 (m \times 2.9 \times 10^{-8}) ÷ d_b
\]

\[
E = (m \div d_b) \cdot [c^2 \times 2.9 \times 10^{-8}]
\]  

(86)

This is a form of the gravitational energy where \( d_b \) is Bohr radius and the factors inside the big bracket are constants which we can factorize them as;

\[
E = 0.6 \cdot m \cdot (m \cdot n) \cdot 6.67 \times 10^{-11} ÷ r
\]  

(87)

Where; \( n \) and \( r \) are constants equal the number of neutrons and radius of the created giant proton respectively (inertial constants for the unit of the giant proton)

**THE FACTOR (5/3);**

Let us write inside the giant proton- the electric field as;

\[
E_e = kc_0 \cdot e^2 \cdot p \div r = A \cdot p^{2/3} = m \cdot c^2 \cdot c_0
\]

And the gravitational field as;

\[
E_G = m^2 \cdot n \cdot G \div r = B \cdot n^{2/3}
\]

Where \( A \) and \( B \) are constants. Integration of collection of \( p \) and of \( n \) gives;

\[
\int A \cdot p^{2/3} \cdot dp = (3/5) \cdot A \cdot p^{2/3}
\]  

(88)

\[
\int B \cdot n^{2/3} \cdot dn = (3/5) \cdot B \cdot n^{2/3}
\]  

(89)

From (61);

\[
(3/5) \cdot kc_0 \cdot e^2 \cdot p \div r = (3/5) \cdot m^2 \cdot n \cdot G \div r
\]

The last form to take the form of the rest form we need;

\[
k \cdot c_0 \cdot e^2 \cdot p \div r = (3/5) \cdot m^2 \cdot (5/3) \cdot n^4 \cdot G \div r
\]  

(90)

where;

\[
(5/3) \cdot n^4 = n.
\]  

(91)

such that, \( n^4 = (1.14 \times 10^{12}) \cdot p \) and then, \( n = 1.9 \times 10^{12} \cdot p \)

This relation gives the explanation of equations (37) and (38)

**CREATION OF THE CREATED GIANT PROTON;**

It is the smallest giant proton so we can create it.

\[
m \cdot c^2 \cdot c_0 = m \cdot v^2 / 2
\]

\[
v = c \cdot \sqrt{2c_0} = 4.08 \times 10^{-4} \text{ m/s}
\]  

(92)

The angular momentum of a particle in Compton state would be;

\[
m \cdot d \cdot (c \cdot \sqrt{2c_0}) = h \cdot \sqrt{2c_o}
\]

If we have a sphere containing;

\[
n = 4.24 \times 10^{21}
\]

\[
p = 2.2 \times 10^9
\]

And if we controlled the density of matter such that the in-between distance \( d = 2.09 \times 10^{-16} \div \sqrt{2c_o} = 1.5 \times 10^{-4} \) m

(93)
The corresponding principle can transform the contents of this sphere as:

\[ m \left( 4.08 \times 10^4 \right) \left( 1.5 \times 10^4 \right) = \hbar \]

\[ m \left( 4.08 \times 10^4 \right) \left( 1.5 \times 10^4 \right) \sqrt{2c_o} = \hbar \sqrt{2c_o} \]

\[ m \left( \sqrt{2c_o} \right) d = \hbar \sqrt{2c_o} \]

From (90); the radius of the sphere = \( R \)

\[ R = 1.5 \times 10^{-4} n^{1/3} = 2.4 \times 10^3 \text{ m.} \]  

**THE CORRESPONDING PRINCIPLE**

This expression in the acknowledge of the giant charge means;

If a sphere has;

\[ v = c \sqrt{2c_o} = 4.08 \times 10^{-4} \text{ m/s} \]

\[ p = 2.2 \times 10^9 \]

\[ n = 4.24 \times 10^{21} \]

Then, the giant charge could be created by this principle.

So, if we have a sphere with homogeneous distribution and with these conditions then we can get a created giant proton.

If the density still the same but \( p^1 = 2p \) then we get a doubled created giant proton.

If the density still constant but we have; \( p^1 = A p \) such that \( A \) is the factor which allows \( p^1 = 2.07 \times 10^{33} \) then we get a giant proton which can orbit a giant electron.

Once the giant proton orbits its giant electron and if we have –say- two giant atoms then the word two means space and space means different density between the inside and outside of the giant charge so the principle not act.

These two giant atoms need to collect beta decay and escape of the internal charges where the gravitational field can pull and collect them.

This suggested principle allows existence of matter in Compton state without gradual condensation.

**THE CREATED GIANT ELECTRON**;

Put the number of electrons in the created giant electron = \( O \) and the inter-particles distances = \( d \)

\[ (e^2 O) \div d \left( 1844n \div p \right)^{1/3} \approx m_p c^2 \div 1844 \]

\[ O = p \div 1844 \]

Number of neutrons in the created giant electron = \( n^1 \)

\[ n^1 = (p \div 1844) \left( 1844 \right. n \div p \left. \right) = n \]

Where \( n \) is the number of neutrons in the created giant proton.

The later to orbit the first as a giant atom in the ground state we need;

\[ O = p \]

And consequently \( n^1 = 1844n \). This means that if the giant proton needs \( u \) of units, then the giant electron needs 1844\( u \).

As in equations; 79, 80, 81, and 96 we can estimate that;

\( A_x \) and \( A_n \) of the created giant electron = \( A_x \) and \( A_n \) of the created giant proton. Consequently, \( c_o \) is equal in both.
THE HIGHER GIANT STATES

The giant atom in its ground state is the smallest inversed giant atom whose giant proton can orbit its giant electron.

The inversed atom is the mathematic basis of the giant atom. The created giant charge is the physical unit of the giant charge while the huge charge is the physical basis of the giant orbit. So the ground state is formed of \( p \) of the huge wave length \( \lambda_u \) or \( p^2/n \) of \( \lambda \) as;

\[
\frac{p^2}{n} \lambda = (\lambda_u) p = 2\pi R.
\]

The higher levels -let us call; the complicated giant charge- could be constructed by the same above basis.

We suggest that; the higher states of the complicated giant proton have number of protons = \( p.d \)

Where \( d \), –in this chapter- means multiplication of \( p \) of the giant proton by a factor lies between 1 and 10 and so it obeys the relation;

\[
1 < d < 10,
\]

Such that, \( p.d \) means protons of the giant proton times \( d \).

We suggest for the complicated giant electron the factor \( D \) where \( D \) obeys the same relation as;

\[
1 < D < 10
\]

Such that, \( D \) means electrons evacuated giant electron (neutral)

From above; we can conclude that the ratio between the mass of the complicated giant electron to that of the complicated giant proton is still = 1844

\[
M_e \div M_p = 1844
\]

In the giant atom (the ground state) \( p = p^1 \) where \( p \) and \( p^1 \) are the number of the protons in the giant proton and that of electrons in the giant electron respectively.

In the complicated atom the system allows that;

Number of the protons in the complicated giant proton = \( p_1 \) while the electrons of the complicated giant electron = \( p_2 \) such that;

\[
P_1 = p d \tag{100}
\]

\[
P_2 = p^1 = p \tag{101}
\]

THE EQUATIONS PACKET OF THE HIGHER STATES

The motion of the giant proton in a higher state is controlled by;

**As a huge proton:**

Its angular momentum obeys;

\[
[\lambda \left( \frac{p^2}{n} \right) d] \left( \frac{v}{d} \right) \left( \frac{m.n}{p} \right) = l \hbar
\]

Where \( \lambda \) = 1.\( \lambda/1 = \lambda \) = Bohr wave length and \( l \) is the level number = 43

The electric force gives;

\[
\left( \frac{m.n}{p} \right) \left( \frac{v^2}{d} \right) = k e^2 \frac{p^1}{R.d^2}
\]

Where \( p^1 \) = number of electrons in the giant electron = \( p \)

We can notice that the mass of the huge proton in the complicated giant proton is still = \( m.n/p \)

**As a giant proton:**

The electric force gives;

\[
[(m.n) d] \left( \frac{v^2}{d} \right)^2 = k (e.p^1) \left( e.p.d \right) \div R.d^2
\]

Where the big bracket is its mass, \( (e.p^1) \) is the number of the electrons in the complicated giant electron while \( (e.p\cdot d) \) is the number of the protons in the complicated giant proton.
THE COMPLICATED GIANT ELECTRON

Its motion is controlled by:

\[ k (e.p^1) (e.p.d) \div (R.d^2)^3 = (m.n^1 D) (v_e/D)^2 \div R_e D^2 \]  

where: \( n^1 = 1844n \)

\[ v_e = v \div 1844 \]
\[ R_e = R \div 1844 \]
\[ 1 < D = d < 10 \]

By substitution as above:

\[ k (e.p^1) (e.p.d) \div (R.d^2)^3 = [(1844D)m.n] (v \div 1844D)^2 \div (R.D^2/1844) \]

Simplification gives:

\[ k (e.p)^2 \div R^2 .d^3 = (m.n) v^2 \div R D^3 \]  

(106)

The angular momentum of the system

\[ L^1 = L_{p^1} + L_e^1 \]

\[ L^1 = (m.n.d) (v/d) (R.d^2) + (m. n^1 D) \]

(107)

\[ (v_e/D) (R_e.D^2) \]

\[ L^1 = d^2.L_p + (D^2.L_p \div 1844) \]  

(108)

\[ L^1 = d^2.L_p (1+ 1 \div 1844) \approx d^2.L_p \approx D^2.L_p \]

(109)

Where; \( L_p \) is the angular momentum of the giant ground state.

The above form is related to the inversed atom base as;

\[ L^1 = d^2.L_p = d^2 (m.n) v. R \]

Substitute in above as; \( R = [r (p^2/n)] \) where \( r \) is Bohr radius.

\[ L^1 = d^2 (.m.v.r) p^2 \]

Since; \( m.v.r = l \hbar \)

\[ L^1 = l.h(p.d)^2 \]  

(110)

The total energy of this higher system = \( E^1 \)

\[ E^1 = (1/2) (m.n.d) (v/d)^2 + (1/2) (m.n^1 D) (v_e/D)^2 + u(R) \]  

(111)

Where, \( u(R) \) is the potential.

\[ E^1 = (E_p/2d) + (E_p/1844) + u(R) \]

\[ E^1 = E/2d + u(R) \]  

(112)

Where \( E \approx E_p \) = the kinetic energy of the giant ground state or approximately the kinetic energy of its giant proton.

We can notice that if \( d \) lies between 1 and 10 which consequently may be fraction of the giant charge yet it is actually arises from multiples of the unit (created giant proton) so actually there is no fractionation of the unit.

THE BASIC DEVIATION FROM QUANTUM MECHANICS

We can summarize the basic deviation of the giant atom from quantum mechanics as follow;

Write the relation; \( 1 < D = d < 10 \) we get the equation packet of the higher states

Put \( D = d = 1 \) we get the equation packet of the giant atom.
Put \((n/p)\) of the giant proton \(= 1.9 \times 10^{12}\) and that of the giant electron \(= 1844\) \((n/p)\) and put the number of the protons = number of electrons = \(p = 1\) you get the equation packet of the huge charge.

Put \((n/p) = 1\) (but we have remember that the electron of the inversed atom is bound by 1836 neutrons) you get the equation packet of the major inversed atom.

Remove the added neutron from the bound electron we get the hydrogen atom system.

**THE END OF COMPTON STATE**

The expression of collection means formation of the giant charge as multiples of the units which we called as the created giant charge. This occurs - in the initial medium which has a constant defined density - by the corresponding principle.

The giant charges themselves not collect by this abstract principle but by;

Beta decay of the neutron of the giant charge and consequently formation of the atoms and much increase of the inter particles distances (end of Compton state) which would – according to equation 29 - results in escape of the charged of the giant charge which would so appears as evacuated giant charge (neutral body)

The above would results in attraction of these neutral bodies by the effective gravitational field to form the solar system.

**THE SOLAR SYSTEM**

We suggest for the solar system the following;

Each planet had its defined sun as units of the giant atoms where these units \(u = M/m\) such that \(M\) is the astronomic mass of the planet while \(m\) is the mass of the giant proton.

The corresponding sun of the planet has the same number of the giant electron

If we speak about the ground state (mercury planet and its sun) then we suggest that;

The giant electrons lied in \((0, y, 0)\) level

Each giant proton orbited it defined giant electron in the level; \(x, 0, z\)

The motion of the units had begun in the same time \((t_0 = \text{constant})\).

The units of the same planet had the same \(R, v\) and \(t_0\) therefore after beta decay they pulled to each other and collect in one body mass. Also do the electrons evacuated giant electrons. So we would have one planet orbits its special sun.

The units of another higher state has another \(v\) and \(R\) therefore they collect in a higher level with radius of orbit \(= R.d^2\)

Because of the radii of the orbits of the units of the different suns are not so away from each other comparative with the units of the different planets so the collect in one mass that is; one sun and nine planets.

Mercury orbit represented the ground state of the solar system motion. It had;

Estimated speed of orbit (as in equation 54) \(= v = 5.06 \times 10^4\) m/s and had estimated radius of orbit \(= R = 5.7 \times 10^{10}\) m

The higher planets obey;

\[ R^3 = R.d^2 \]
\[ v^3 = v.d. \]

The actual astronomic radius of orbit of mercury coincides with our estimation while the actual astronomic speed of the orbit \(= 4.74 \times 10^4\) m/s. Actually the natal speed \(v\) was about \(5 \times 10^4\) m/s. That is because it is known that the sun losses gradually some of matter in production of heat. It is known that it lost about seven percent of its natal mass\(^{(4)}\) If the present mass of the sun \(= 1.99 \times 10^{30}\) k.gm.
and its natal mass was $A$

$$A - 0.07 = 1.99 \times 10^{30} \text{ k.gm.}$$

$$A (1 - 0.07) = 1.99 \times 10^{30}$$

$$A = 2.14 \times 10^{30} \text{ k.gm.}$$

$$2.14 \times 10^{30} G \div 5.7 \times 10^{10} = v^2$$

$$v = 5 \times 10^4 \text{ m/s.}$$

**THE RATIO MS ÷ Σ Mp;**

It is the ratio between mass of the sun and the summed masses of all planets.

Our estimation gave; $\frac{M_s}{\Sigma M_p} = 1844$

The astronomic ratio = 800 where the sun natal mass = $2.14 \times 10^{30}$ k.gm.

Therefore there is error in our estimation = $1844 \div 800 = 2.3$

So we suggest for this error the following:

There was about 5 orbiting giant protons for each 2 giant electrons

The spatial motion allows the following configuration;

- $(x, 0, z)$ and $[x, \Delta y, (z - \Delta z)]$ for a giant electron and;
- $(x, 0, z)$, $[x, \Delta y, (z - \Delta z)]$ and $[x, -\Delta y, (z - \Delta z)]$ for another next one.

**CONCLUSION**

The solar system has many parameters which ensure that it was created from giant atoms. We can create the smallest giant charge with $R = 1.5 \times 10^{-4} n^{1/3} = 2.4 \times 10^3$ m.

**REFERENCES**

[4] Sackmann, Juliana (February 2003), our sun v, A Bright Young sun consistent with Helioseismology and warm temperature on ancient Earth and Mars, the astrophysics J 583(2), 1024 – 10.39
